

Vascutouch Consent

We may not be able to remove all the unwanted vessels at one appointment; this is done for safety. Thus, a series of treatments may be necessary (2-3 sessions). You may also be genetically predisposed to vascular blemish formation and may develop more of them over time. For instance, if you have fair skin and spend a lot of time outdoors, you may develop more vascular lesions. In such cases, you will likely need to visit us annually or as needed to address new vessel formations.

It is important for you to understand the disadvantages before undergoing this procedure. Initially, several treatments may be required, and we should not expect 100% removal of all vessels, especially if you have a large number of vascular blemishes. Results for facial and upper body capillaries will be visible quickly, with most vessels dissipating within a day or two. However, you may experience some redness for up to 48 hours following treatment. For a few days after treatment, the area may appear to have dilated vessels remaining, which are darker in color. This is usually temporary and caused by inflammation and reduced oxygenated blood flow. Skin flushing and redness vary based on individual skin types. Some people may experience minimal redness, while others may have a more pronounced flushed appearance after treatment. Additionally, tiny crusts may form on the face and body, which may last 7-10 or more days.

In some cases, temporary darkening (pigmentation) of the skin where the vessels have been removed may occur. While we have not encountered permanent pigmentation, marks can persist for up to six months. We do have products available to help expedite the disappearance of pigmentation, if necessary. On the face, pigmentation may appear as tiny brown dots. Although pigmentation is expected to be temporary, in rare cases, it may become permanent. Sores or ulcers rarely occur as a result of post-treatment infection; therefore, it is crucial to carefully follow aftercare instructions and keep the treated area clean. Infection can lead to dot-like scarring.

Lastly, we have observed that prior treatments with sclerotherapy, laser, or hyfrecator can create "treatment-resistant" blood vessels that may require a significantly higher number of treatments. In some instances, certain treatments may be unsuccessful. Please ensure to discuss any prior treatments with your skincare expert.

Photographs are mandatory for documenting the progress of the procedure. I acknowledge and agree to have photographs taken, and I also consent to their use for training and educational purposes. I have read the above information and understand the potential risks, limitations, and benefits of the treatment.

I understand these risks, and I consent to having the procedure performed.
